

Supplementary Materials

Bio-based solutions consisting of arbuscular mycorrhizal fungi (AMF) with contrasting life-history strategies differently affect health-promoting compounds in fruits of field-grown tomato by changing arbuscule occurrence and diversity of AMF in roots

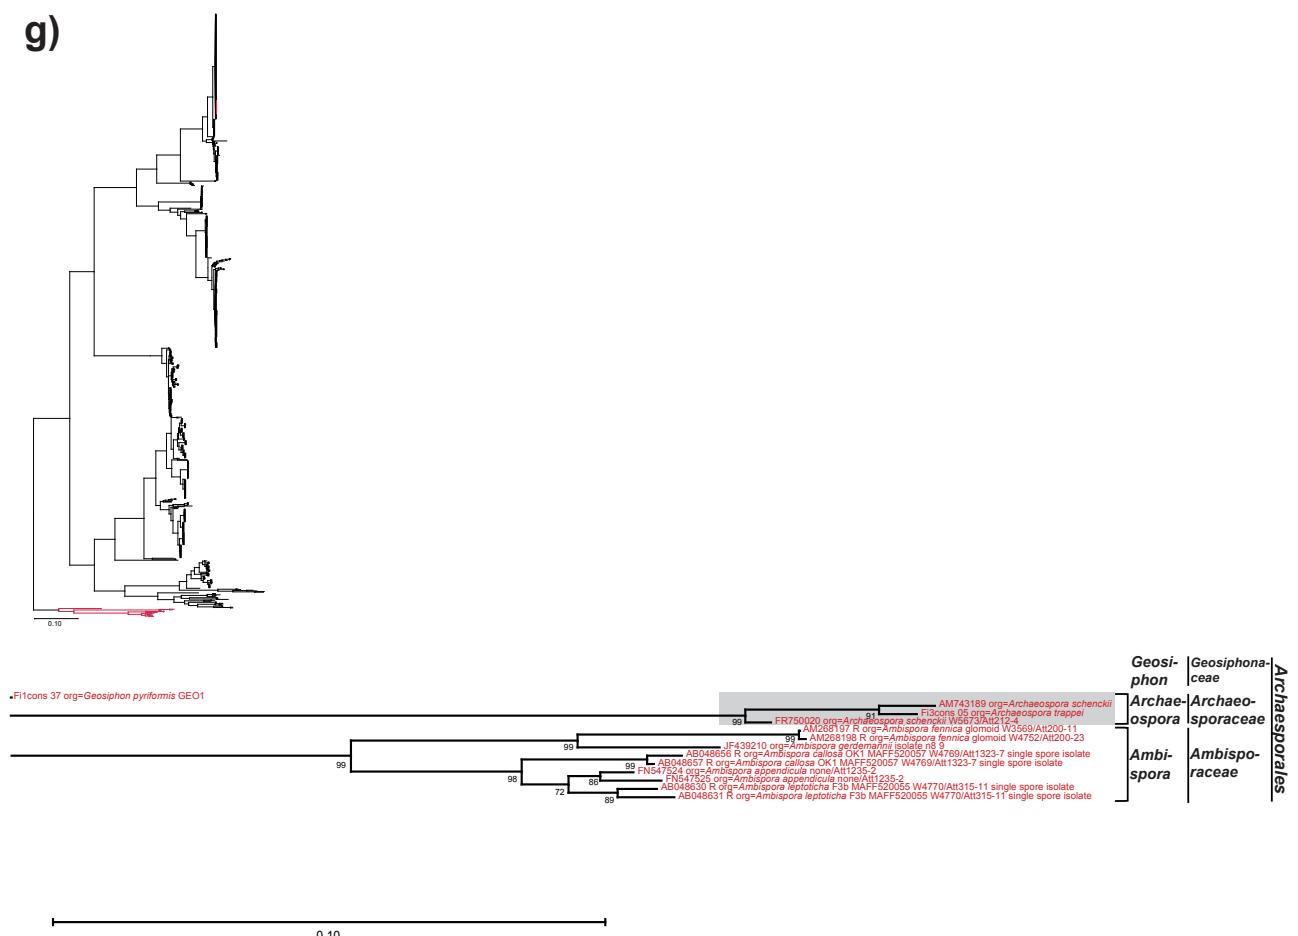

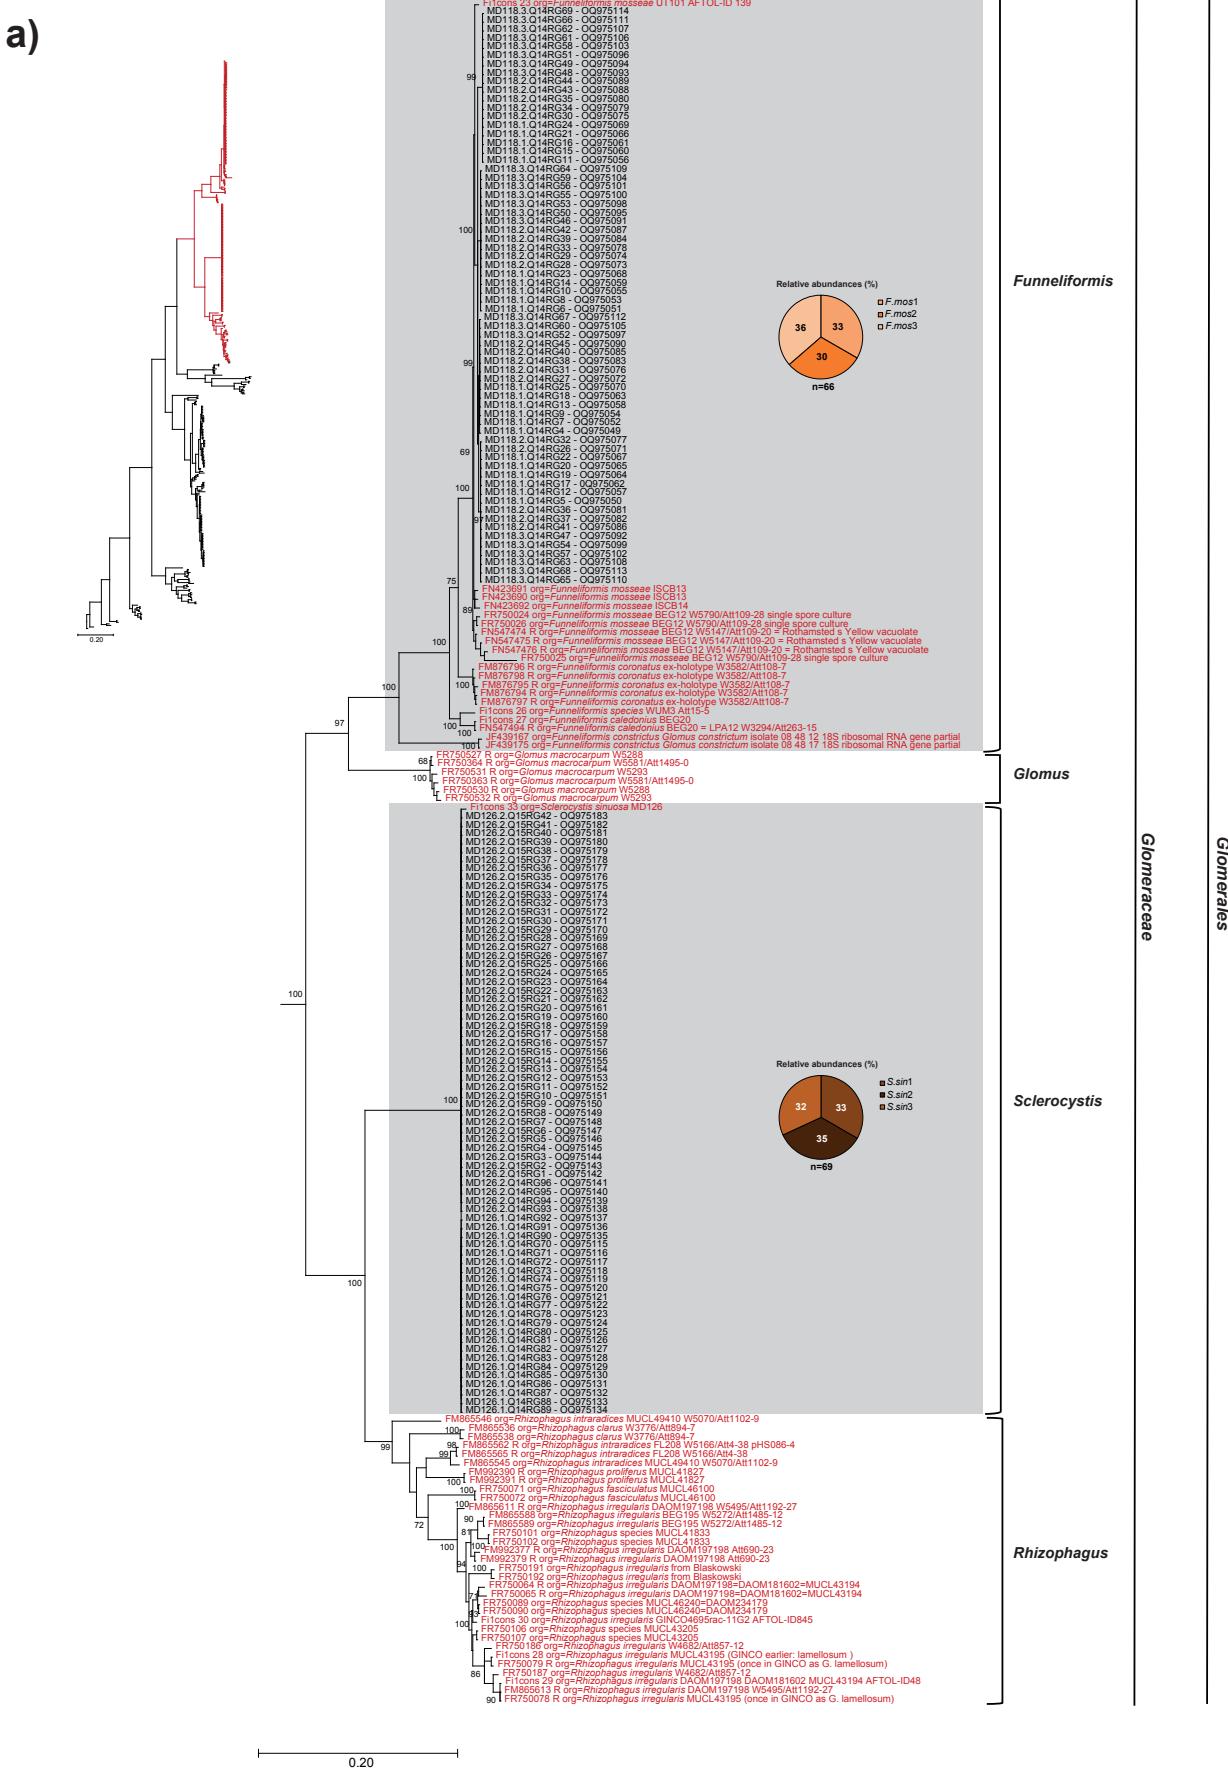

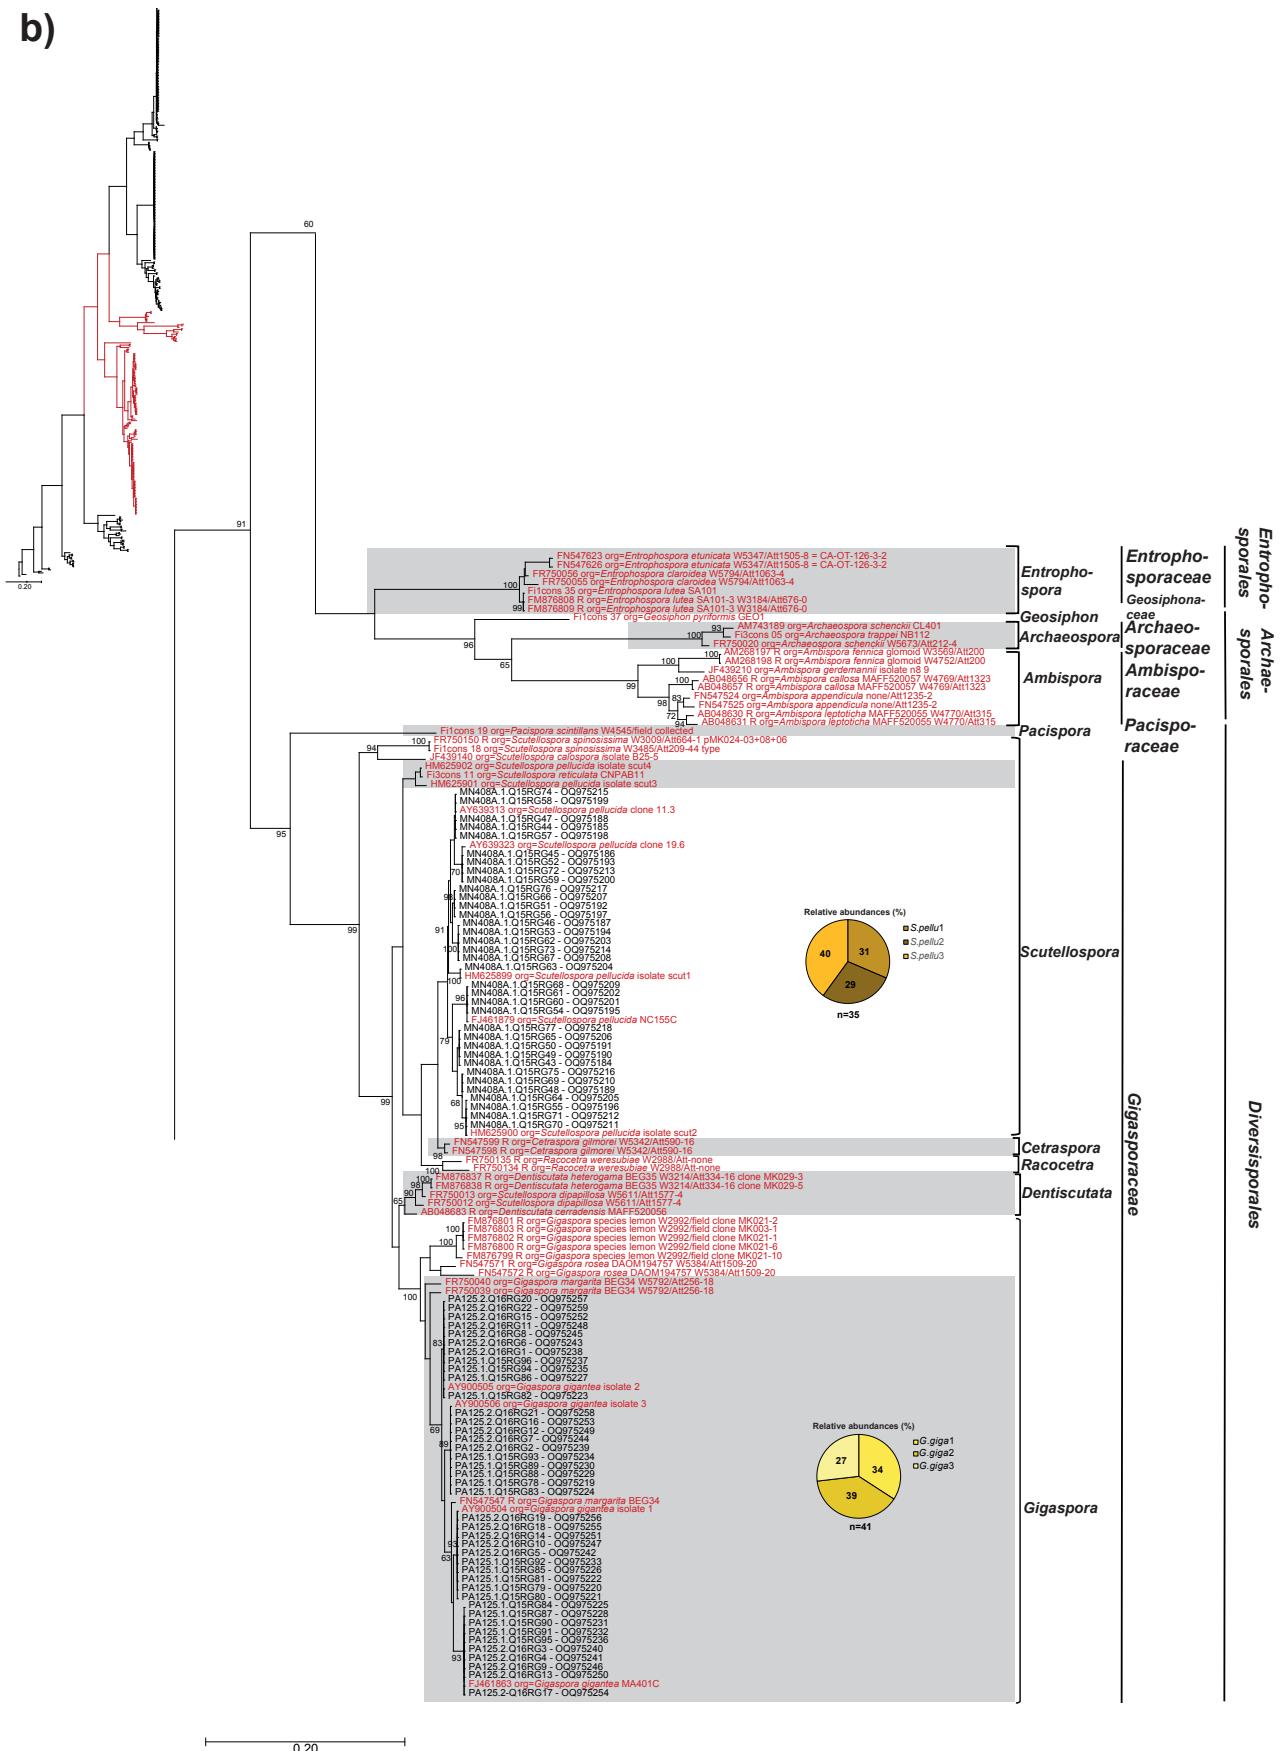

Fig. S1 Maximum Likelihood (ML) tree of sequences of arbuscular mycorrhizal fungi (AMF; Glomeromycota) retrieved at 2nd harvest within the roots of tomato (*Solanum lycopersicum* L.) var. Pisanello inoculated with AMF at nursery and mock inoculated (control, -M). Inocula were: *Gigaspora gigantea* (*G.giga*) and *Scutellospora pellucida* (*S.pelli*) belonging to Gigasporaceae, and *Funneliformis mosseae* (*F.mos*) and *Sclerocystis sinuosa* (*S.sin*) belonging to Glomeraceae. The ML tree is based on sequences obtained from the amplification of part of the SSU, the complete ITS region, and ca. 0.8 kb of the LSU rRNA gene (ca. 1500-bp-long fragment) (Krüger et al. 2009). Fragments were amplified using the primer pair SSUMAf–LSUMAr and then the SSUMCf and LSUMBr as nested primers. The tree is composed by 765 newly generated sequences belonging to 11 phylotypes, plus 161 reference sequences from NCBI. Bootstrap values (based on 1 000 replicates) are shown at the nodes. The Tamura-Nei model was used in the analysis (Tamura and Nei 1993). The scale bar indicates substitutions per site. Portions of the ML tree are shown (a-g). Pie charts represent the percentage of clones of each phylotype in the three replicates of each treatment. The sequences of *Paraglomus occultum* IA702 was used as outgroup. The newly generated sequences are black coloured, while the reference sequences from NCBI are red coloured. The newly generated sequences are named as follows (e.g. MD126.II.3.Q11Pis13): MD126 refers to the AM fungal isolate (see Table S1); II refers to the second harvest; 3 refers to the number of replicate plot; Q11 refers the number of the plate of the Sanger Run; Pis refers to variety Pisanello; 13 refers to the number of the clones within the specific AM fungal treatment and replicate plot. Evolutionary analyses were conducted in MEGA 11 (Stecher et al. 2020; Tamura et al. 2021). All representative newly generated sequences were deposited in the NCBI Sequence Read (SRA) database as SUB13362899.

The ML tree is based on sequences obtained from the amplification of part of the SSU, the complete ITS region, and ca. 0.8 kb of the LSU rRNA gene (ca. 1500-bp-long fragment) (Krüger et al. 2009). Fragments were amplified using the primer pair SSUMAf–LSUMAr and then the SSUMCf and LSUMBr as nested primers. The tree is composed by 211 newly generated sequences belonging to four phylotypes, plus 158 reference sequences from NCBI. Bootstrap values (based on 1 000 replicates) are shown at the nodes. The Tamura-Nei model was used in the analysis (Tamura and Nei 1993). The scale bar indicates substitutions per site. Portions of the ML tree are shown (a-c). Pie charts represent the percentage of clones of each phylotype in the three replicates of each treatment. The sequences of *Paraglomus occultum* IA702 was used as outgroup. The newly generated sequences are black coloured, while the reference sequences from NCBI are red coloured. The newly generated sequences are named as follows (e.g. MD118.3.Q14RG69): MD118 refers to the AM fungal isolate (see Table S1); 3 refers to the number of replicate plot; Q14 refers the number of the plate of the Sanger Run; RG refers to variety Rio Grande; 69 refers to the number of the clones within the specific AM fungal treatment and replicate plot. Evolutionary analyses were conducted in MEGA 11 (Stecher et al. 2020; Tamura et al. 2021). All representative newly generated sequences were deposited in the NCBI Sequence Read (SRA) database as SUB13324118 and numbers of accession are OQ975049-OQ975259.

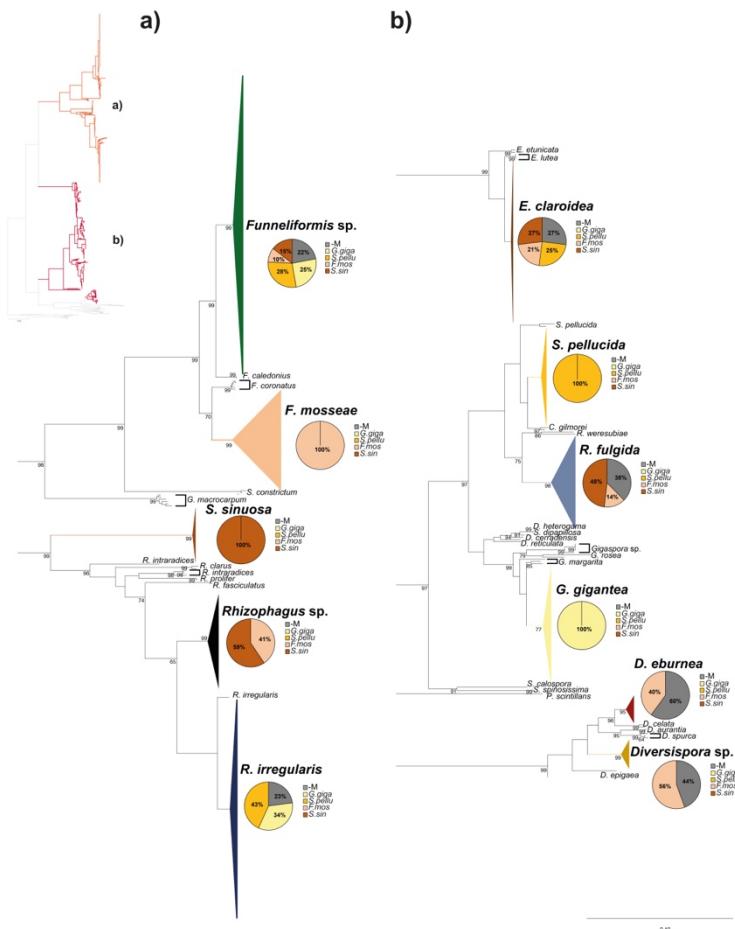

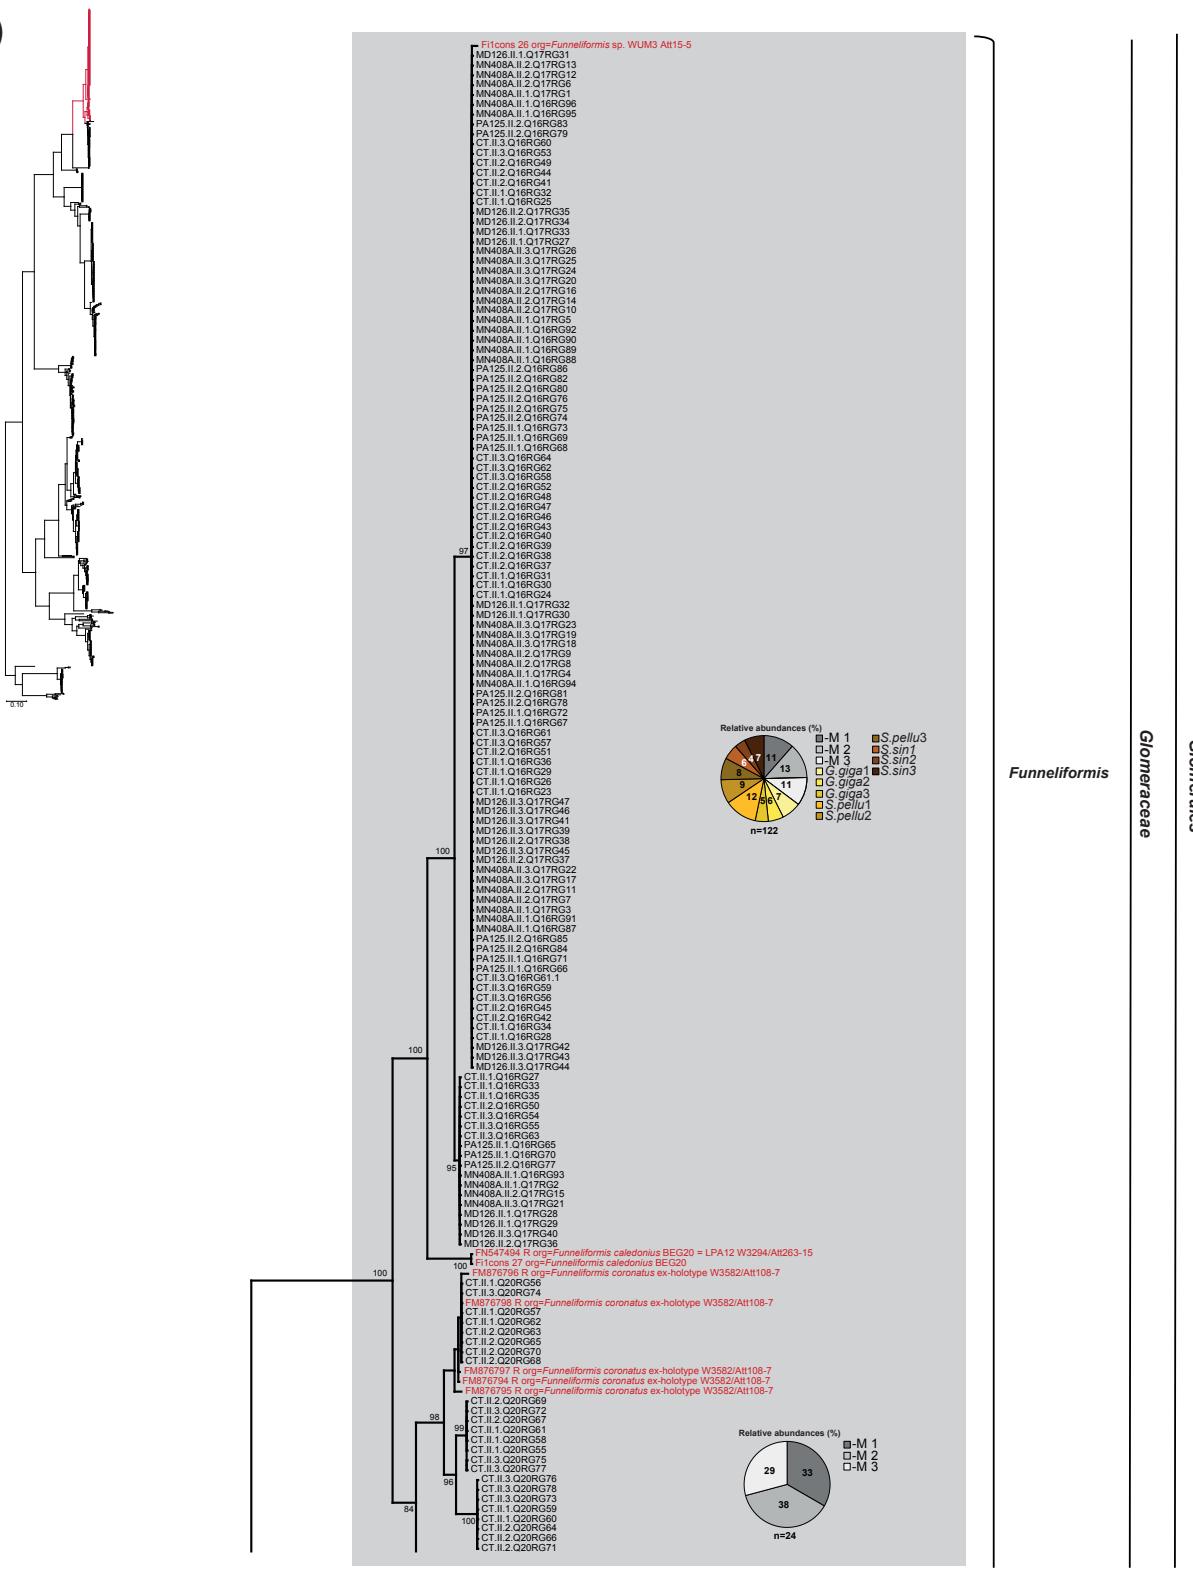

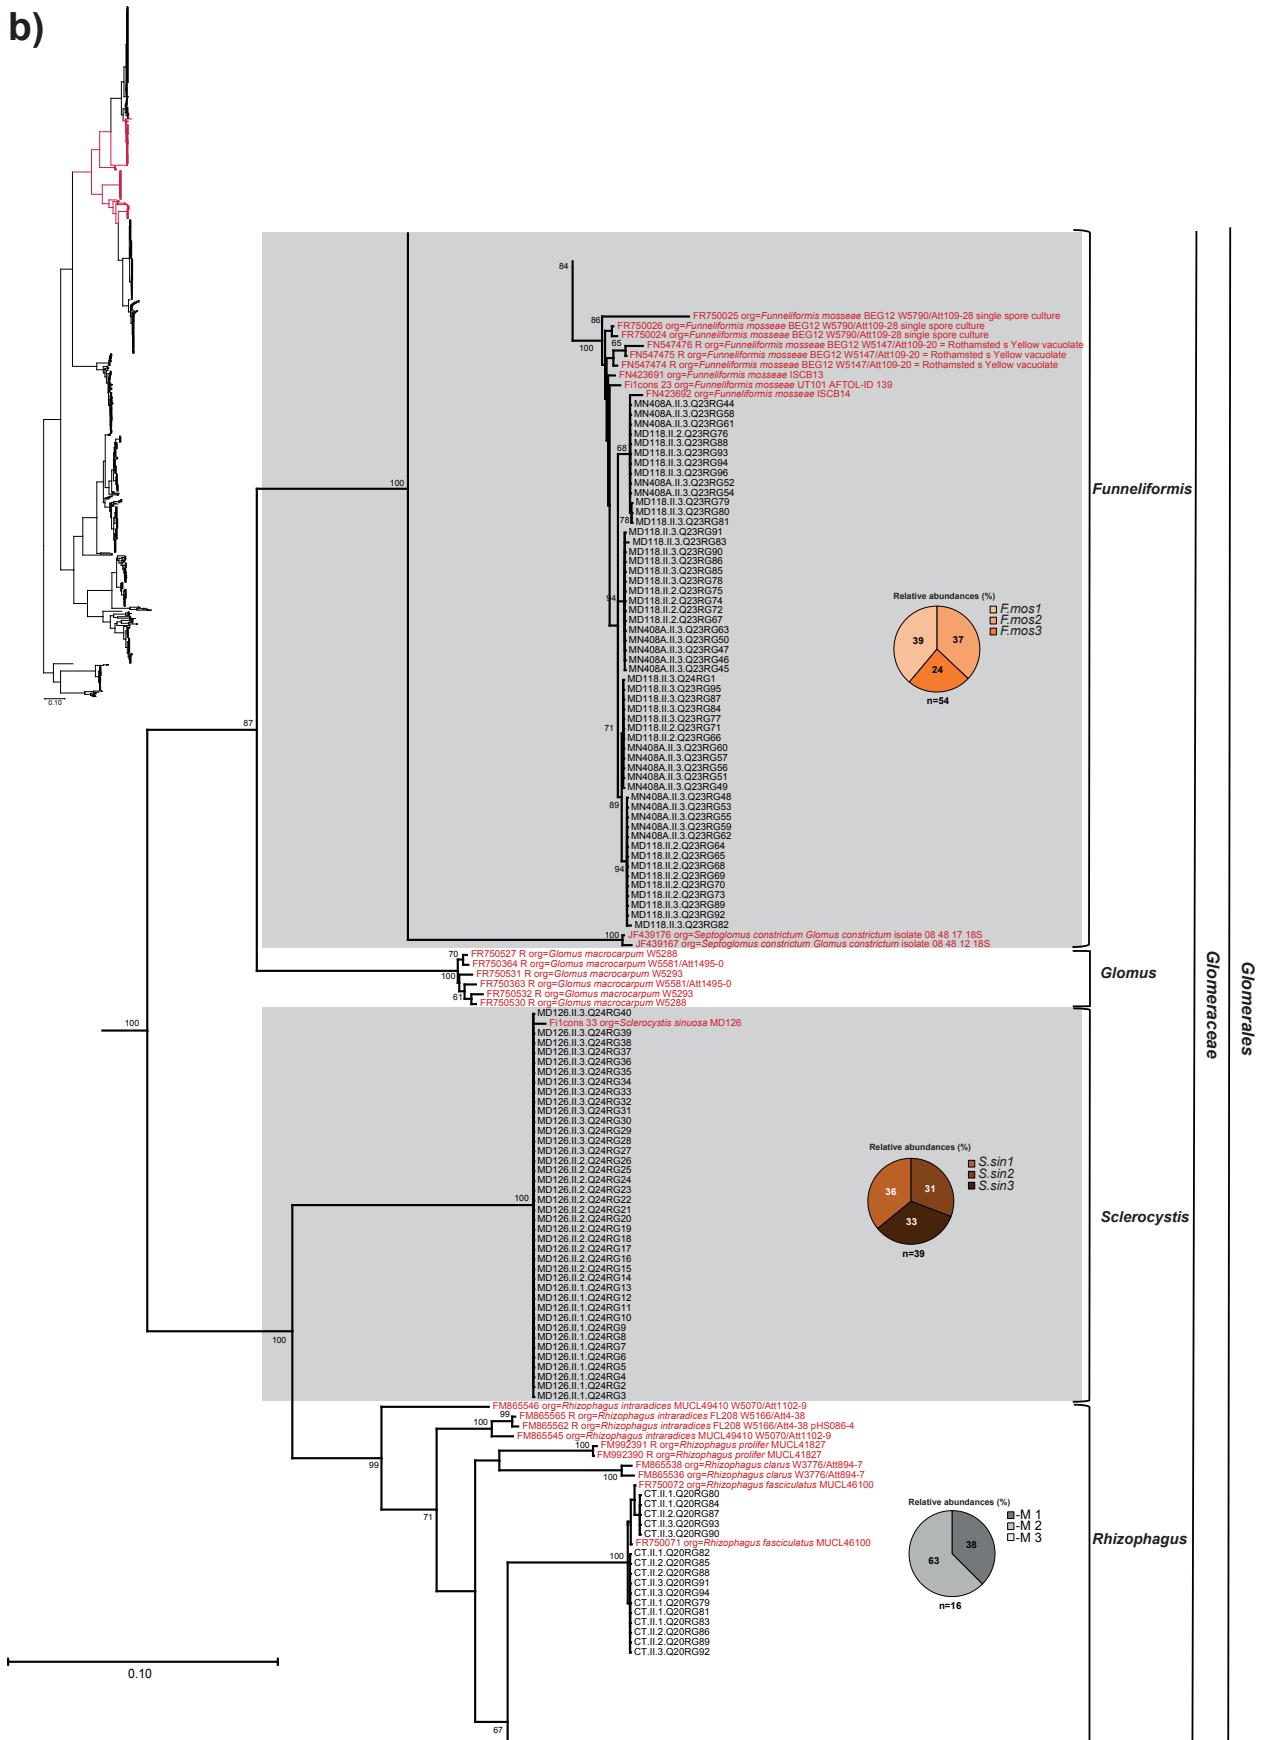

Fig. S3 Collapsed Maximum Likelihood (ML) tree of sequences of AMF (Glomeromycota) retrieved at transplanting within the roots of tomato (*Solanum lycopersicum* L.) var. Rio Grande inoculated with AMF at nursery and mock inoculated (control, -M). Inocula were: *Gigaspora gigantea* (*G.giga*) and *Scutellospora pellucida* (*S.pellu*) belonging to Gigasporaceae, and *Funneliformis mosseae* (*F.mos*) and *Sclerotostysis sinuosa* (*S.sin*) belonging to Glomeraceae. The ML tree is based on sequences obtained from the amplification of part of the SSU, the complete ITS region, and ca. 0.8 kb of the LSU rRNA gene (ca. 1500-bp-long fragment) (Krüger et al. 2009). Fragments were amplified using the primer pair SSUMAf–LSUMAr and then the SSUMCf and LSUMBr as nested primers. The tree is composed by 211 newly generated sequences belonging to four phylotypes, plus 158 reference sequences from NCBI (see Fig. S2 for the whole ML tree including the accession numbers of the newly generated and reference AM fungal sequences). Bootstrap values (based on 1 000 replicates) are shown at the nodes. The Tamura-Nei model was used in the analysis (Tamura and Nei 1993). The scale bar indicates substitutions per site. Portions of the ML tree are shown (a) and (b). Collapsed phylotypes are shown by coloured branches and triangles. Pie charts represent the relative abundances of each phylotype (calculated as number of clones in each treatment divided by total number of clones of the phylotype and multiplied by 100). The sequences of *Paraglomus occultum* IA702 was used as outgroup. The newly generated sequences are highlighted in boldface, see collapsed branches. Evolutionary analyses were conducted in MEGA 11 (Stecher et al. 2020; Tamura et al. 2021).

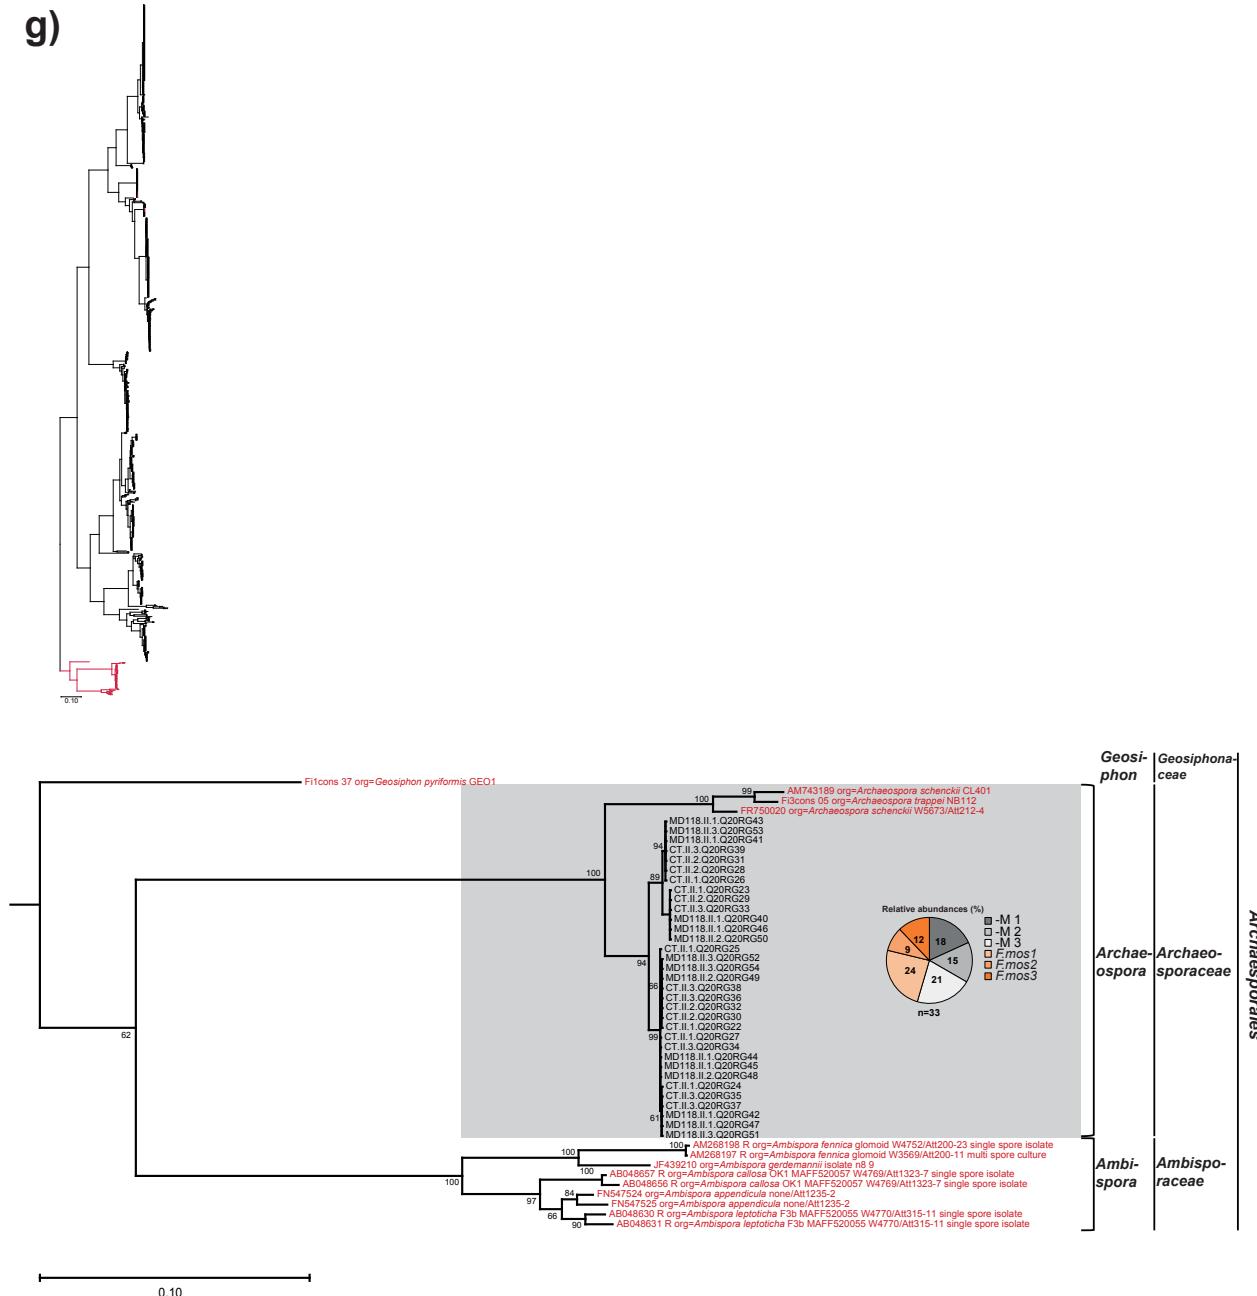

Fig. S4 Maximum Likelihood (ML) tree of sequences of AMF (Glomeromycota) retrieved at 2nd harvest within the roots of tomato (*Solanum lycopersicum* L.) var. Rio Grande inoculated with AMF at nursery and mock inoculated (control, -M). Inocula were: *Gigaspora gigantea* (*G.giga*) and *Scutellospora pellucida* (*S.pellu*) belonging to Gigasporaceae, and *Funneliformis mosseae* (*F.mos*) and *Sclerocystis sinuosa* (*S.sin*) belonging to Glomeraceae. The ML tree is based on sequences obtained from the amplification of part of the SSU, the complete ITS region, and ca. 0.8 kb of the LSU rRNA gene (ca. 1500-bp-long fragment) (Krüger et al. 2009). Fragments were amplified using the primer pair SSUMAf–LSUMAr and then the SSUMCf and LSUMBr as nested primers. The tree is composed by 788 newly generated sequences belonging to 15 phylotypes, plus 162 reference sequences from NCBI. Bootstrap values (based on 1 000 replicates) are shown at the nodes. The Tamura-Nei model was used in the analysis (Tamura and Nei 1993). The scale bar indicates substitutions per site. Portions of the ML tree are shown (a-g). Pie charts represent the percentage of clones of each phylotype in the three replicates of each treatment. The sequences of *Paraglomus occultum* IA702 was used as outgroup. The newly generated sequences are black coloured, while the reference sequences from NCBI are red coloured. The newly generated sequences are named as follows (e.g. MD126.II.1.Q17RG31): MD126 refers to the AM fungal isolate (see Table S1); II refers to the second harvest; 1 refers to the number of replicate plot; Q17 refers the number of the plate of the Sanger Run; RG refers to variety Rio Grande; 31 refers to the number of the clones within the specific AM fungal treatment and replicate plot. Evolutionary analyses were conducted in MEGA 11 (Stecher et al. 2020; Tamura et al. 2021). All representative newly generated sequences were deposited in the NCBI Sequence Read (SRA) database as SUB13375274.

Fig. S5 Effect of AM fungal inoculation on the relative abundance of AMF phylotypes in roots of tomato (*Solanum lycopersicum* L.) var. Pisanello (a) and var. Rio Grande (b). Plants were inoculated at nursery and mock inoculated (control, -M). Inocula were: *Gigaspora gigantea* (G.giga) and *Scutellospora pellucida* (S.pellu) belonging to Gigasporaceae, and *Funneliformis mosseae* (F.mos) and *Sclerocystis sinuosa* (S.sin) belonging to Glomeraceae.

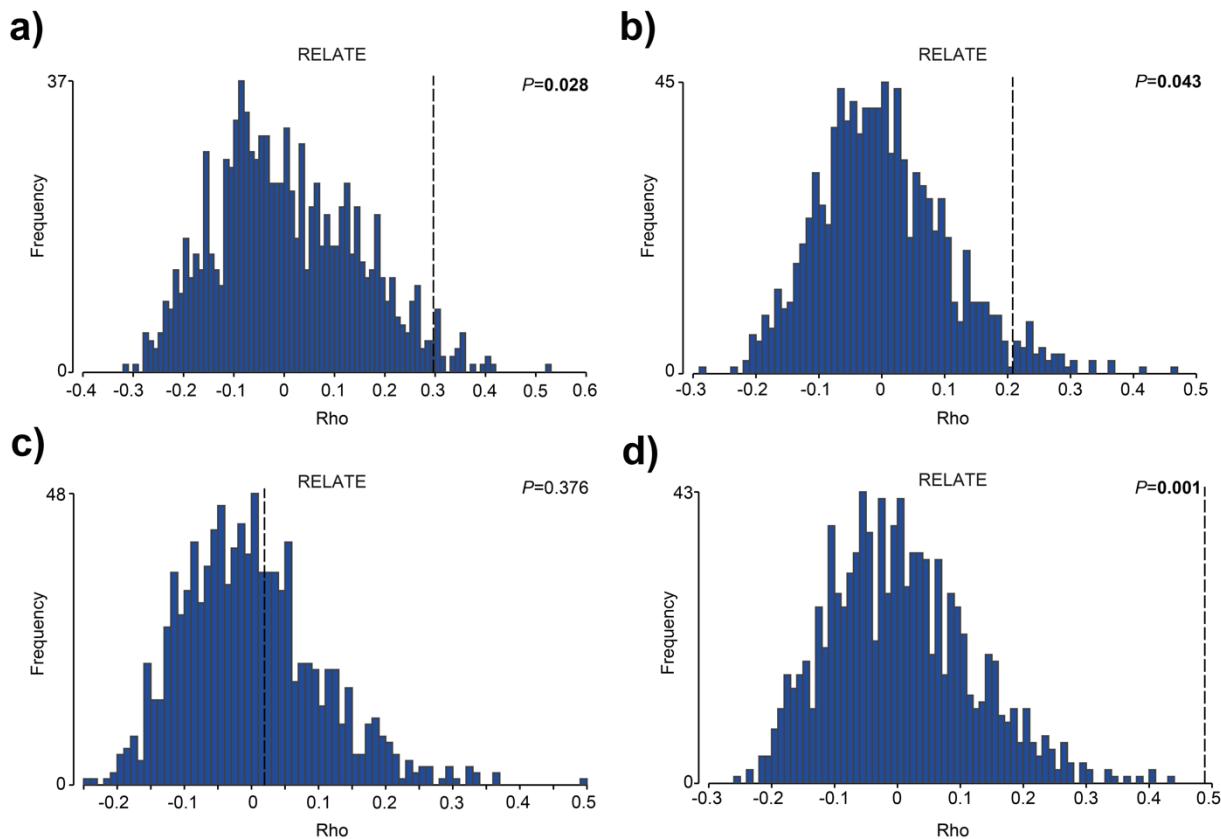

Fig. S6 RELATE analysis based on Spearman rank and 999 permutations for testing the significance of the relationship between the two matrices: the matrix of AM fungal colonisation traits and fruits quality parameters in var. Pisanello (a) and var. Rio Grande (b); the matrix of AMF community structure and fruits quality parameters in var. Pisanello (c) and var. Rio Grande (d) ($\rho = 1$ perfect relationship) (Clarke and Warwick 2001). Significant P values are highlighted boldface. The analysis was carried out using PRIMER 7 and PERMANOVA + software (Anderson et al. 2008; Clarke and Gorley 2015).
